The Yocto Project is a Linux Foundation workgroup, which produces tools (SDK) and processes (configuration, compilation, installation) that will enable the creation of Linux distributions for embedded software, independent of the architecture of embedded software (Raspberry Pi, i.MX6, and so on).

[Yocto for Raspberry Pi](#)

The Yocto Project is a build system that allows developers to make custom Linux distributions matching their exact needs. I've already shown how to build a 12MB Compressed image for the Raspberry Pi with Yocto, but the Raspberry Pi 2 has recently been added to the project, so I've tried to build it too in a machine running Ubuntu 14.04.

Yocto on the Raspberry Pi. Yocto supports a number of embedded hardware platforms, one of the most popular being the BeagleBone Black (4). At a retail price of around US\$60 it is quite affordable. Yocto can also be built for the Raspberry Pi, which is even lower in cost than the BeagleBone.

To do so, we naturally need to connect a Yocto-Display and a Yoctopuce sensor. In this instance, we used a Yocto-Light-V3 and a Yocto-MaxiDisplay-G. Now that we tested that our code works under Windows, let's see how to run the same application on a Raspberry Pi. Generating a version for Raspberry Pi
